Laboratory of Pharmaceutics and Pharmaceutical Technology Development, Faculty of Pharmacy, Universitas Indonesia, Depok, 16424, INDONESIA.

ABSTRACT

Background: One of the natural products that have many benefits is green tea (*Camellia sinensis* L.). It can be used to maintain health because of its high antioxidant activity from epigallocatechin gallate (EGCG). However, EGCG has a low ability to penetrate through the skin due to its hydrophilicity. The aim of this study is to improve the penetration of EGCG through the skin by lipid nanovesicle, namely ethosome. **Methods:** Ethosomes were made using thin layer hydration method. Ethosomes were formulated with different concentration, equal to 1% (F1), 1.5% (F2), and 2% (F3) of EGCG from green tea leaves extract. They were characterized, then a chosen formula would be formulated into a gel dosage form (ethosomal gel). A gel without ethosome (non-ethosomal gel) was prepared as a control. Both of them were evaluated their penetration enhancement ability using Franz diffusion cells with the abdomen skin of *Sprague-Dawley* rats. **Results and Discussion:** Based on the results, F1 had a spherical shape, Dv90 129.00 ± 0.00 nm, polydispersity index 0.05 ± 0.00, zeta potential at -62.6 ± 5.05 mV, and the highest entrapment efficiency of 54.39 ± 0.03 %. The cumulative

amount of EGCG penetrated from ethosomal and non-ethosomal gel were 1364.28 ± 56.32 µg/cm² and 490.17 ± 2.60 µg/cm², respectively (p<0.05). The flux value of ethosomal and non-ethosomal gel were 56.97 ± 2.06 µg/cm². hour and 31.09 ± 0.29 µg/cm². hour, respectively. **Conclusion:** It can be concluded that ethosomal gel can increase the penetration of EGCG from green tea leaves extract.

Key words: EGCG, Epigallocatechin Gallate, Ethosomes, Franz Diffusion Cell, Green Tea Leaves Extract, *In vitro* Penetration Test.

INTRODUCTION

One of the natural product that has many benefits is green tea leaves. Green tea leaves contain polyphenols from flavonoid groups, which the type is catechin.¹ Catechin has advantages in the treatment of diseases and prevention of the damaged skin due to UV-B exposure. Moreover, it has anti-inflammatory and antioxidant activity.² The most abundant content of catechin in green tea leaves is epigallocatechin gallate (EGCG).³ However, if EGCG is administered orally, it has a low bioavailability due to enzymatic and first metabolism reactions.³ A study showed that EGCG has low absorption in the gastrointestinal tract (GIT) (less than 5% absorbed).⁴ In addition, the most important factor that can limit the bioavailability of polyphenol from green tea leaves is an efflux pump mechanism in the GIT by MRP1 and MRP2 proteins.⁵ Other researchers showed that a conjugated catechin after hepatic metabolism does not have an antioxidant effect. These problems can be overcome by choosing another route of drug administration. It is transdermal drug delivery system. Transdermal drug delivery system is a drug delivery through the skin into the systemic circulation.⁶ This route can avoid GIT problem, first-pass metabolism, and fluctuations of drug levels in the blood. Additionally, the transdermal administration is non-invasive and can be applied easily.⁷ However, transdermal drug delivery has limitations regarding penetration, especially for drugs that are hydrophilic.⁶ A strategy to enhance drug penetration to the skin is by making nanovesicle, namely ethosome. Ethosome is a lipid-based nanovesicle that is formulated of *phospholipids*, a high concentration of alcohols (20-45%), and water. It has a better ability to increase drug penetration than conventional liposomes.⁸⁻¹⁰ This ability is due to the presence of high concentration of ethanol that can make the *ethosome* more deformable and elastic than a

conventional liposome. Also, the ethanol can be a penetration enhancer.^{10,11} Ethosome is a non-invasive vehicle, so it is safe to use it on the skin.^{8,9} Ethosome can be formulated into a semi-solid dosage form, for instance, gel dosage forms. The water content in the gel has a function to moisturize the skin and is comfortable to be used.¹²

As a hydrophilic compound (Log P = 0.48), EGCG has a problem to penetrate through the skin.³ Entrapping EGCG in the vesicles will increase its penetration through the skin and its stability from oxidation reaction. Thus, formulating green tea leaves into a lipid-based nanovesicle is one of the best ways to increase its penetration.

In this study, ethosomes of green tea leaves extract (*Camellia sinensis* L. Kuntze) were formulated, then a chosen formula was incorporated into a gel dosage form. *In vitro* penetration test was performed using Franz diffusion cells with female *Sprague-Dawley* rats skin as a membrane. In comparison, the control gel formulation of green tea leaves extract was made. Furthermore, the EGCG chemical analysis was performed by using a TLC-densitometry method.

MATERIALS AND METHODS

MATERIALS

Green tea leaves extract (*Camellia sinensis* L. Kuntze) (Andy Biotech Co. Ltd., China), EGCG standard (Sigma-Aldrich, Singapore), Lipoid P 30 with purity of 97% *phospholipids* containing 30% *phosphatidylcholine* (kindly provided by Lipoid GmbH, Germany), solvents and other chemical reagents are analytical grade.

EGCG Assay in Green Tea Leaves Extract

A calibration curve was made with a standard solution of EGCG, and the sample solution concentration was 1000.0 µg/mL. The solution was then spotted on a silica gel plate and eluted using dichloromethane-acetone-formic acid (8:7:1) as the eluent. The plates were then analyzed by TLC scanner at a wavelength of 275 nm.

Antioxidant Activity Test of Green Tea Leaves Extract

The positive reference solution of ascorbic acid and green tea leaves extract solution were made in different concentration. DPPH 100 µg/mL (1.0 mL) and methanol (2.0 mL) were added into 1.0 mL of each sample solution. The blank solution was made. The mixture was shaken for a few seconds, then incubated at a temperature of 37°C for 15 min. The antioxidant activity was determined by measuring the absorbance of each sample by UV-Vis spectrophotometer with an optimum wavelength of 521 nm.

Ethosome Formulation

Ethosome formulations can be seen in Table 1. *Ethosome* was prepared using mechanical dispersion method. Firstly, Lipoid P 30 was diluted with dichloromethane. Then the dissolved phospholipid was poured into the round-bottom flask. Dichloromethane in the flask was then evaporated using rotary vacuum evaporator at a temperature of 37 ± 2°C. Evaporation was done to form a thin film on a round bottom flask. Nitrogen gas flowed into the thin layer, and it is stored in the refrigerator up to 24 sh. The thin layer then hydrated with a hydroalcoholic solution containing green tea leaves extract at 40°C. Once the ethosomal suspension was formed, ultrasonication was done for 2 min.

Ethosome Characterization

Morphology

Ethosomes morphology was analyzed by transmission electron microscope (TEM, JEOL JEM 1400). Samples were shed on a carbon-coated copper grid, the droplet then dried at room temperature and colored using

phosphotungstic acid solution. After drying, they were viewed under a microscope at 80,000 magnification and the acceleration voltage of 100 kV.

Particle Size Distribution, Polydispersity Index, and Zeta potential

Particle size distribution and zeta potential of *ethosome formulas* were measured by Dynamic light scattering (DLS) particle size analyzer with a computerized system (Malvern, Zetasizer). Zeta potential measurements were also performed. Each measurement was performed three times.

The Entrapment Efficiency

The ethosome suspension was taken 1.0 mL, then centrifuged at 13000 rpm for two times of 30 min. The supernatant was discarded, and the precipitate was collected and extracted with chloroform and ethanol. The solution was then spotted on a silica gel plate and eluted. The plates were then analyzed by TLC scanner. Entrapment efficiency was calculated by the formula:

$$\%EE = \frac{\text{EGCG concentration measured}}{\text{Total EGCG in the suspension}} \times 100\%$$

Gel Preparation

Carbomer was dispersed in demineralized water for 24 h. The dispersed carbomer was then homogenized. *Triethanolamine* was then added into the dispersion. Then the mixture was homogenized to obtain a gel base. Propylene glycol was added to the gel base, then was homogenized. Once the gel was formed, ethosomal green tea leaves extract was added into the basis for ethosomal gel formula (EG), and the green tea extract was dispersed for not-ethosomal gel (NEG). Both gels were then homogenized for 15 min. Both of gel formulations as can be seen in Table 2.

Physicochemical Evaluation of Gel Dosage Forms

Physicochemical evaluations of gel, including organoleptic test (color, odor, syneresis), homogeneity, pH, viscosity and rheology properties, were conducted.

Table 1: Ethosome formulas

Materials	Concentration (%)		
	F1	F2	F3
Green tea extract	Equal to EGCG 1	Equal to EGCG 1.5	Equal to EGCG 2
Lipoid P 30	4	4	4
Ethanol 95%	20	20	20
Propylene glycol	5	5	5
Phosphate buffer pH 5.5	ad 100	ad 100	ad 100

Note: (F1) Ethosome formula 1, (F2) Ethosome formula 2 and (F3) Ethosome formula 3

Table 2: Gel formulation

Materials	Concentration % (w/w)	
	EG	NEG
Carbomer	1	1
Triethanolamine	0.6	0.6
Propylene glycol	12.5	12.5
Ethosomal green tea leaves extract	Equal to EGCG 0.5	-
Green tea extract	-	Equal to EGCG 0.5
Demineralized water	Ad 100	Ad 100

Note: (EG) Ethosomal gel and (NEG) Non-ethosomal gel

Gel Stability Test

Gel stability test was performed by storing the gel at low ($4 \pm 2^\circ\text{C}$), room ($25 \pm 2^\circ\text{C}$), and high ($40 \pm 2^\circ\text{C}$) temperature. During 8-weeks, organoleptic, homogeneity, and pH were checked properly. Viscosity and rheology property were seen in the storage room temperature after 8 weeks.

In vitro Penetration Test

The abdomen skin of female *Sprague-Dawley* rats aged 2-3 months was used as a membrane in the test. All of the methods for sacrificing the animals have been approved by Ethical Clearance Committee of Cipto Mangunkusumo Hospital, Faculty of Medicine, Universitas Indonesia No. 418/UN.2F1/ETIK/2016. The test was performed by using Franz diffusion cells with a diffusion area of 2.01 cm^2 and a 15 ml compartment volume. The receptor compartment was filled with phosphate buffer pH 5.5 and stirred with a magnetic stirrer at speed of 250 rpm. Then, the skin was placed in the donor compartment receptor with the position of the stratum corneum facing upwards. A sample of 1.0 g was applied to the skin surface. Then, at several time intervals (2, 4, 6, 8, 10, 12, 14, 16, 18, 20, and 24 h) samples (3.0 mL) was taken from receptor compartment using a syringe and receptor compartment was refilled with the same amount of phosphate buffer pH 5.5. Next, the sample was inserted into the vial and its concentration measured by TLC-densitometry.

Statistical Analysis

Statistical analysis of data was performed using GraphPad Prism 6.0 via unpaired t-tests with significance level was set at $P < 0.05$.

RESULTS AND DISCUSSION

EGCG Assay in Green Tea Leaves Extract

Eluent dichloromethane-acetone-formic acid (8: 7: 1) produced a peak with Rf of 0.54. Dichloromethane-acetone-formic acid (8: 7: 1) gave a good Rf value because the solvent mixture could provide a good separation between EGCG and the other components in the extract. This separation produced sharper spots with appropriate terms of Rf; i.e., Rf is 0.2-0.8.¹³ Based on the analysis, the area obtained is then calculated into the calibration curve, so the content of EGCG in the extract was $53.20 \pm 0.28\%$.

Antioxidant Activity Test of Green Tea Leaves Extract

The smaller the IC_{50} , the higher the antioxidant activity of a compound. The IC_{50} value of green tea leaves extract was $6.00 \mu\text{g/mL}$, while the IC_{50} value of ascorbic acid was $2.37 \mu\text{g/mL}$. A compound has very strong antioxidant properties when it has a value an $\text{IC}_{50} < 10 \mu\text{g/mL}$.¹⁴ Based on this statement, it can be concluded that both of vitamin C and the green tea leaves extract has a very strong antioxidant property.

Ethosome Formulation

The main components of ethosomes were phospholipid and ethanol. Phospholipid that has a similar structure to the lipid bilayer of the skin and the use of ethanol as penetration enhancers were expected to increase the permeability of the membrane of the vesicle to the skin. They also make ethosomes appropriate as transdermal delivery.¹¹ Vesicles containing ethanol tends to have a thinner membrane, so the addition of propylene glycol was necessary to hold the leakage of layers as well as penetration enhancers.¹⁵ The use of phosphate buffer at pH 5.5 has been selected because EGCG is stable at low pH ($< \text{pH } 6$). The liquid suspension was then sonicated to decrease the particles size. Sonication performed within two min to prevent the outbreak of the vesicles.

Morphology

Based on the obtained analysis, all ethosomes prepared had a spherical shape. The results were shown in Figure 1. The resulting shape resembles the shape of ethosomes from the previous study, unilamellar and spherical.¹⁶

Particle Size Distribution, Polydispersity Index, and Zeta Potential

All results for particle size, zeta potential, and polydispersity index can be seen in Table 3. Vesicle size that can pass through the deepest skin layer must be smaller than 300 nm.¹⁷ It shows that the particle size is an important parameter in transdermal drug delivery. F1 had a particle size distribution between 50.75 to 220.2 nm, with 78.82 nm as the most dominant particle size. F2 has a particle size distribution between 58.77 to 255 nm, with 91.28 nm as the most dominant particle size. F3 has a particle size distribution between 122.4 to 295.3 nm, at 190.1 nm as the most dominant particle size. Based on the value of $\text{Dv}90$ F1 ($129.00 \pm 0.00 \text{ nm}$), F2 ($155.33 \pm 2.08 \text{ nm}$) and F3 ($232.67 \pm 2.52 \text{ nm}$). They showed that the less active substance that was incorporated into the ethosome

Figure 1: Morphology of vesicles at 80,000 magnification. (A) F1, (B) F2 and (C) F3.

Table 3: Summary of ethosomes characterization results

Sample	Morphology	Dv90 (nm)	Polydispersity Index	Zeta Potential (mV)	Entrapment Efficiency (%)
F1	Spherical shape	129.00 ± 0.00	0.05 ± 0.00	-66.33 ± 2.32	54.39 ± 0.03
F2	Spherical shape	155.33 ± 2.08	0.07 ± 0.02	-61.30 ± 2.60	39.98 ± 0.16
F3	Spherical shape	232.67 ± 2.52	0.25 ± 0.03	-60.50 ± 2.43	33.32 ± 0.29

Note: All values were represented as Mean ± SEM (n=3). (F1) Ethosome formula 1, (F2) Ethosome formula 2 and (F3) Ethosome formula 3

formulation, the smaller the particle size of the ethosome. It had a correlation to the ratio between the concentration of the active substance and ethanol. A high concentration of ethanol will reduce the thickness of the membrane vesicles, so the vesicles size will be smaller.⁹ The theory was proven by the results.

Another important physical property is the value of polydispersity index (PDI). PDI is the degree of heterogeneity of particles. The smaller or closer to zero of the PDI value, the less degree of heterogeneity of particle size. PDI with good value is <0.7.¹⁸ The smaller the particle size, the smaller the value of IPD. F1 (0.05 ± 0.00), F2 (0.07 ± 0.02) and F3 (0.25 ± 0.03).

In addition, zeta potential was also measured. A good value of zeta potential is greater than +30 mV or smaller than -30 mV.¹⁸ Zeta potential for each formula were F1 (-66.33 ± 2.32 mV), F2 (-61.30 ± 2.60 mV) and F3 (-60.50 ± 2.43 mV). All formulas had zeta potential which is smaller than -30 mV, so all three formulations have a good value of zeta potential. Zeta potential is affected by pH, conductivity, and additives were charged. The negative charge produced from the ethanol in the system can prevent the aggregation of vesicles due to electrostatic repulsion and resistance force. The negative charge was caused by the vibration of sonication.¹⁶

The Entrapment Efficiency

The entrapment efficiency obtained for F1, F2, and F3 were 54.39 ± 0.03%, 39.98 ± 0.16%, and 33.32 ± 0.29%, respectively. Based on the percentage entrapment efficiency, the absolute value of the extract in ethosome respectively in F1, F2, and F3 were 255.65 ± 0.14 mg; 281.84 ± 1.15 mg; and 313.20 ± 2.76 mg. F1 was chosen to be incorporated into gel dosage form because there will be less remaining free extract that was not entrapped in the ethosome than F2 or F3. So, it would be more efficient. The entrapment efficiency will increase with the increase of the phospholipid concentration.¹⁹ F1 with the lowest concentration of EGCG had the best entrapment efficiency because *phospholipids* at a concentration of 4% can only entrap the active substances about 255.65 to 313.20 mg. Therefore, the addition of the active substance concentration in this study cannot significantly improve the efficiency of entrapment.

Formulation of Selected Ethosome

Formula that has a spherical morphology, a high percentage of entrapped drug, nano-sized (<300 nm), polydispersity index <0.7 and the zeta potential is more negative than -30 or more positive than +30 mV was chosen to be incorporated into gel dosage form. Based on the characterization, the selected formula was F1 because it had a spherical shape; D_{mean} particle size by volume was 90.53 ± 0.32 nm; polydispersity index of 0.05 ± 0.00; zeta potential -62.6 ± 5.05 mV; and the highest percentage of drug entrapped (54.39 ± 0.03%).

Physicochemical Evaluation of Gel Dosage Forms

EG color was pale orange (Pantone 1205 U), while the NEG was transparent orange (Pantone 143 U).²⁰ Both gels appeared homogeneous when smeared on a glass slide. The pH value of the EG and NEG at week

0 were 5.80 and 5.89, respectively. The pH value suits the pH balance of the skin, i.e. 4.5-6.5.

Viscosity measurements at a speed of 20 rpm for EG and NEG were 3100 cps and 2300 cps, respectively. EG has higher viscosity due to the presence of phospholipid in formulations. Both gels were thixotropic with a plastic flow. Plastic flow curve does not pass through the point (0,0) and has a yield value. Yield value is a straight line extrapolated from the curve straight to the axis of the shear stress. Preparations that have plastic flow will not flow when the shear stress does not pass the yield value. Thixotropic indicate that the decline curve on the left ascending curve which means that when a shear stress, the structure takes the time to get back to the original condition.

Gel Stability

Based on organoleptic and homogeneity observations of EG and NEG at low (4 ± 2 °C), room (25 ± 2 °C), and high (40 ± 2 °C) temperature, the organoleptic and homogeneity did not change. In observation of color, it did not change at the low-temperature storage. However, at room temperature and high temperature, there was discoloration on EG and NEG to a darker orange. The color changing was caused by the oxidation of EGCG in the gel. This oxidation process occurs due to the absence of additional antioxidants in the gel formulation.

Based on the measurements of pH for 8 weeks at different temperatures, it was obtained that the pH fluctuation was in the range of 5.40 to 6.13. The pH decreasing at room temperature and high temperature were caused by the oxidation of EGCG that increased the acidity. Additionally, the pH increase in storage at high temperatures caused the release of TEA from the gel matrix that increases the alkalinity. The changes were acceptable because the pH range is still at the acidity of the skin (4.5-6.5).

The results of viscosity measurements at the speed of 20 rpm on EG and NEG were 2800 cps and 2100 cps, respectively. Based on the results, there was a decrease in the viscosity of the EG and NEG caused by the oxidation of EGCG, thus increase the acidity of the gels. These results were in line with the fall of the pH stability at room temperature. EG and NEG retained the plastic thixotropic flow properties.

In vitro Penetration Test

After the penetration test for 24 h with 13 points of sampling, it was obtained the cumulative amount of EGCG penetrated for EG was 1364.28 ± 56.32 µg/cm², while the NEG was 490.17 ± 2.60 µg/cm² (Figure 2) (p < 0.05). Cumulative percentage of penetrated EGCG for EG and NEG were 54.42 ± 2.25% and 19.55 ± 0.10%, respectively. Based on these results, the EG had a greater amount of EGCG penetrated than the NEG. EGCG absorption through the skin in EG and NEG have a lag time of 1.71 ± 0.05 and 14.25 ± 0.03 h. The flux value that was generated from EG and NEG was 56.97 ± 2.06 µg.cm⁻².h⁻¹ and 31.09 ± 0.2 µg.cm⁻².h⁻¹. Based on these results it can be concluded that the EG has better flux value. The flux value indicates that the penetration rate of EGCG was faster from EG than NEG. The increased of EGCG penetrated that was contained in ethosome occur with a variety of mechanisms. The ethosome size was smaller than 300 nm, that made the ethosome can pass through

Figure 2: Cumulative of EGCG penetrated. All values were represented as Mean \pm SEM (n=3). (*) $p < 0.05$ compared to control group.

the membrane skin to the deeper layers.¹⁶ The effects of ethanol and propylene glycol in the suspension as penetration enhancers will cause an interaction with the lipid molecules of the stratum corneum. It will increase the fluidity of the lipid bilayer. Then, this leads to the increase in permeability of the stratum corneum to the drug.²¹

The EGCG entrapped in ethosome, containing phospholipid (having the same structure with the lipid bilayer skin) and ethanol (causing the fluidity of vesicles), was another reason for increasing of EGCG penetrated.¹¹ The vesicles that were formulated into a gel dosage form can be a controlled release delivery.²² The amount of EGCG penetrated from NEG was less due to the hydrophilicity of EGCG, making it difficult to penetrate through the skin. The additional of ethanol in NEG only helps the penetration of EGCG in small quantities. These results are in line with previous research, which was EGCG was not penetrated to the receptor medium and simply deposited in the skin.²³ Another most important factor that can affect drug penetration is partition coefficient.²⁴ When EGCG is entrapped in the vesicle, the coefficient partition of phospholipid is similar with lipid in the stratum corneum. Thus, penetration of EGCG from EG was higher than NEG.

CONCLUSION

It can be concluded that ethosomal gel can increase the penetration and stability of EGCG from green tea leaves extract.

ACKNOWLEDGEMENT

The authors are highly thankful to Universitas Indonesia who had given a financial support for this research, particularly for PITTA Research Grants 2016 No. 1823/UN2.R12/HKP.05.00/2016.

CONFLICT OF INTEREST

Authors declare that there is no conflict of interest.

ABBREVIATION USED

EGCG: Epigallocatechin gallate; **MRP:** Multidrug-resistance-associated protein; **GIT:** Gastrointestinal tract; **UV:** Ultra Violet; **TEM:** transmission electron microscope; **%EE:** Entrapment efficiency; **IC:** Inhibitor concentration; **PDI:** Polydispersity index.
